To: Himanshu Mishra &lt;himanshumishra3112@gmail.com&gt;

**State and Strategy design:**

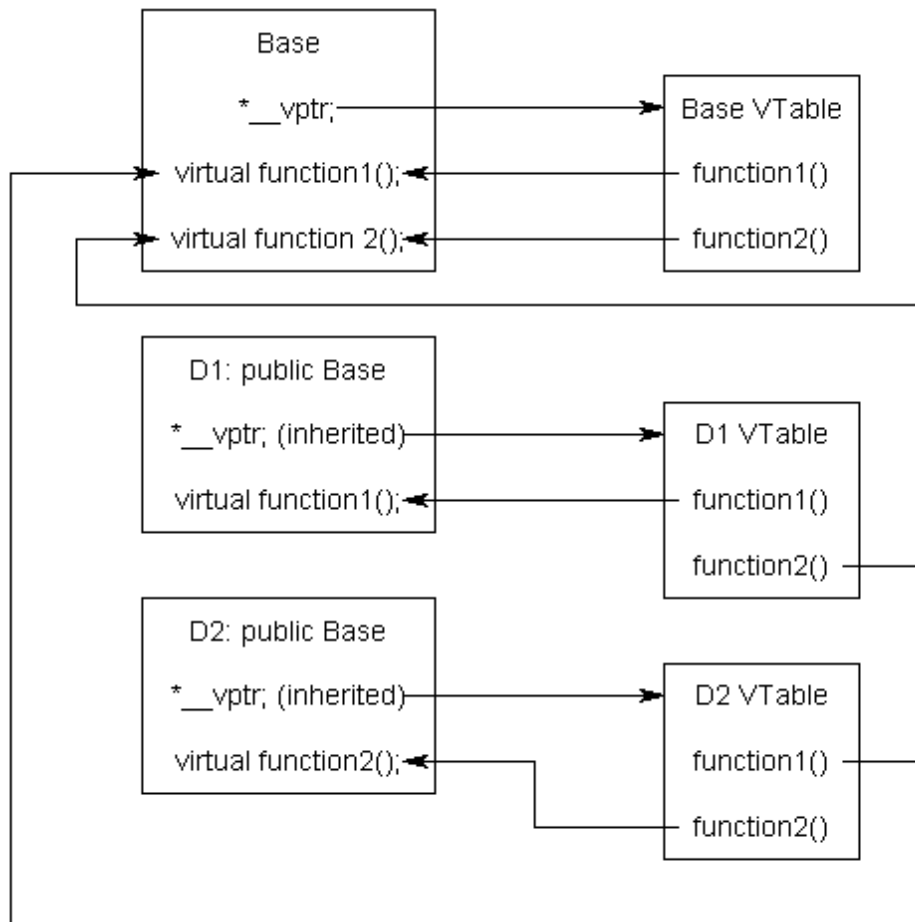

The Strategy pattern is really about having a different implementation that accomplishes (basically) the same thing, so that one implementation can replace the other as the strategy requires. For example, you might have different sorting algorithms in a strategy pattern. The callers to the object does not change based on which strategy is being employed, but regardless of strategy the goal is the same (sort the collection).

The State pattern is about doing different things based on the state, while leaving the caller relieved from the burden of accommodating every possible state. So for example you might have a `getStatus()` method that will return different statuses based on the state of the object, but the caller of the method doesn't have to be coded differently to account for each potential state.

The difference simply lies in that they solve different problems:

- The *State* pattern deals with **what** (state or type) an object is (in) -- it encapsulates state-dependent behavior, whereas
- the *Strategy* pattern deals with **how** an object performs a certain task -- it encapsulates an algorithm.

**vTable Concept:**

## STL

### ->Sequence containers

#### ->vector:

- \* Dynamic array which grows in one direction
- \* Direction (--->)
- \* Elements can be randomly accessed
- \* Recommended way of traversing is through iterator(faster)
- \* Dynamically allocated contiguous block of memory
- \* fast insert/remove at the end:  $O(1)$
- \* slow insert/remove at the beginning or in the middle:  $O(n)$
- \* slow search:  $O(n)$
- \* Cache advantage

#### ->deque

- \* Direction <--- or --->
- \* Random access.
- \* fast insert/remove at the both ends
- \* Slow insert/remove at the middle:  $O(n)$

- \* slow search:  $O(n)$

- >list

- \* Doubly linked list.
- \* Fast insert/remove at any place inside list
- \* Slow search(slower than vector)
- \* cache misses
- \* take more memory
- \* No random access
- \* big advantage: splice()

- >forward list

- \* one direction

- >array

- \* size can not be changed
- \* two array of integer may have different type

- > **Associative**

- >set

- >map

- > **Unordered**

- >set

- >map

**Common API:**

```
cont.begin()
cont.end()
cont.empty()
cont.size()
cont.swap()
cont.clear()
```

**Storage qualifiers in C++:**

- Const - This variable means that if the memory is initialised once, it should not be altered by a program.
- Volatile - This variable means that the value in the memory location can be altered even though nothing

in the program code modifies the contents.

iii.) Mutable - This variable means that a particular member of a structure or class can be altered even if a particular structure variable, class, or class member function is constant.

### Adapter Design

Target: Defines the interface that the client uses.

Adapter: It uses (adapts) the Adaptee's interface and exposes the Target interface to the client.

Adaptee: This is the object whose interface needs to be adapted.

Client: It uses the Adaptee functionality via the adapter interface, i.e., Target.

### **Observer Design Pattern**

**Observer Pattern's** intent is to define a **one-to-many** dependency between objects so that when one object changes state, all its dependents are notified and updated automatically. The **subject** and **observers** define the one-to-many relationship. The observers are dependent on the subject such that when the subject's state changes, the observers get notified. Depending on the notification, the observers may also be updated with new values.

"The need for **dynamic\_cast** generally arises because you want to perform derived class operation on a derived class object, but you have only a pointer or reference-to-base" said Scott Meyers in his book "Effective C++".

## What is Visitor Pattern?

The "**visitor**" design pattern is a way of separating an algorithm from an object structure. The basic idea is that you have a set of element classes that form an object structure. Each of these element classes has an "**accept**" method that takes a visitor object as an argument. The visitor is an interface that has a different "**visit**" method for each element class. The "accept" method of an element class calls back the "visit" method for its class. Separate concrete visitor classes can then be written that perform some particular operations.

You can think of these visit methods as methods not of a single class, but rather methods of a pair of classes: the concrete visitor and the particular element class. Thus the visitor pattern simulates double dispatch in a conventional single dispatch object-oriented language such as Java or C++.

The **Visitor Design Pattern** allows you to decouple the logics and the data structures and while applying the logics to the data structures. With this pattern, you can build classes that focus only on the data structures without knowing the logics that will be applied to the structure. At the same time, you can build classes that concentrate solely on the logics that will be applied to the structure without knowing what the structure looks like. The benefit is

that the evolution of the logics and the structures can vary independently.

## Builder Pattern

- Builder pattern is useful when you want to build a complex object. Intent of this pattern is to separate the construction of object from its representation.
- Abstract the construction of object and then derived concrete implementations will give respective construction parts.
- The director makes sure that the product (complex object) is properly created using the builder interface and the parts are built with correct order.

```
#include <iostream>
#include <string>
#include <queue>

using namespace std;

// Product
class Meal {
public:
    Meal() {}
    ~Meal() {}

    void setMealItem(string mealItem) { mMeal.push(mealItem); }
    void serveMeal() {
        int i = 1;
        while(!mMeal.empty()) {
            cout << " Serve item " << i++ << ":" << mMeal.front() << endl ;
            mMeal.pop();
        }
    }

private:
```

```
        queue <string> mMeal;
};

// Builder
class MealBuilder {
public:
    MealBuilder() {}
    ~MealBuilder() {}

    const Meal& getMeal() { return mMeal; }
    virtual void buildStarter() = 0;
    virtual void buildMainCourse() = 0;
    virtual void buildDessert() = 0;

protected:
    Meal mMeal;
};

// Director: Makes sure the right sequence of food is prepared and served.
class MultiCuisineCook {
public:
    MultiCuisineCook():mMealBuilder(NULL) {}
    ~MultiCuisineCook() { if (mMealBuilder) delete mMealBuilder;}

    void setMealBuilder(MealBuilder *mealBuilder) {
        if (mMealBuilder) delete mMealBuilder;
        mMealBuilder = mealBuilder;
    }

    const Meal& getMeal() { return mMealBuilder->getMeal(); }

    void createMeal() {
        mMealBuilder->buildStarter();
        mMealBuilder->buildMainCourse();
        mMealBuilder->buildDessert();
    }

private:
    MealBuilder *mMealBuilder;
};

// Concrete Meal Builder 1
class IndianMealBuilder : public MealBuilder {
public:
    IndianMealBuilder() {}
```

```
~IndianMealBuilder() {}

void buildStarter() { mMeal.setMealItem("FriedOnion");}
void buildMainCourse() { mMeal.setMealItem("CheeseCurry");}
void buildDessert() { mMeal.setMealItem("SweetBalls");}

};

// Concrete Meal Builder 2
class ChineeseMealBuilder : public MealBuilder {
public:
    ChineeseMealBuilder() {}
    ~ChineeseMealBuilder() {}

    void buildStarter() { mMeal.setMealItem("Manchurian");}
    void buildMainCourse() { mMeal.setMealItem("FriedNoodles");}
    void buildDessert() { mMeal.setMealItem("MangoPudding");}

};

// Concrete Meal Builder 3
class MexicanMealBuilder : public MealBuilder {
public:
    MexicanMealBuilder() {}
    ~MexicanMealBuilder() {}

    void buildStarter() { mMeal.setMealItem("ChipsNSalsa");}
    void buildMainCourse() { mMeal.setMealItem("RiceTacoBeans");}
    void buildDessert() { mMeal.setMealItem("FriedIcecream");}

};

int main()
{
    MultiCuisineCook cook;

    cout << "Build a Chineese Meal!" << endl;
    cook.setMealBuilder(new ChineeseMealBuilder());
    cook.createMeal();

    Meal chineeseMeal = cook.getMeal();
    chineeseMeal.serveMeal();

    cout << "Build a Mexican Meal!" << endl;
    cook.setMealBuilder(new MexicanMealBuilder());
    cook.createMeal();
}
```

```
Meal mexicanMeal = cook.getMeal();
mexicanMeal.serveMeal();

return 0;
}
```

Output:-

```
Build a Chinese Meal!
Serve item 1:Manchurian
Serve item 2:FriedNoodles
Serve item 3:MangoPudding
Build a Mexican Meal!
Serve item 1:ChipsNSalsa
Serve item 2:RiceTacoBeans
Serve item 3:FriedIcecream
```

## What is template design pattern?

- Template pattern is a behavioral design pattern.
- This has nothing to do with C++ templates as such.
- Template patterns is a common form in object oriented programming. Having an abstract base class (one or more pure virtual functions) is a simple example of template design pattern.
- In the template pattern, parts of program which are well defined like an algorithm are defined as a concrete method in the base class. The specifics of implementation are left to the derived classes by making these methods as abstract in the base class.
- The method which implements the algorithm is also referred as template method and the class which implements this methods as the template class.

## Demonstrate the usage of template design pattern

```
#include <iostream>
using namespace std;

// Base class
// Template class
class Account {
public:
    // Abstract Methods
    virtual void Start() = 0;

    virtual void Allow() = 0;

    virtual void End() = 0;

    virtual int MaxLimit() = 0;

    // Template Method
    void Withdraw(int amount) {

        Start();

        int limit = MaxLimit();
        if ( amount < limit ) {
            Allow();
        }
        else {
            cout << "Not allowed" << endl;
        }

        End();
    }
}
```

```
};

// Derived class
class AccountNormal : public Account {
public:
    void Start() {
        cout << "Start ..." << endl;
    }

    void Allow() {
        cout << "Allow ..." << endl;
    }

    void End() {
        cout << "End ..." << endl;
    }

    int MaxLimit() {
        return 1000;
    }
};

// Derived class
class AccountPower : public Account {
public:
    void Start() {
        cout << "Start ..." << endl;
    }

    void Allow() {
        cout << "Allow ..." << endl;
    }

    void End() {
        cout << "End ..." << endl;
    }

    int MaxLimit() {
        return 5000;
    }
};

int main() {
    AccountPower power;
    power.Withdraw(1500);
}
```

```
AccountNormal normal;  
normal.Withdraw(1500);  
}
```

**OUTPUT:-**

```
Start ...  
Allow ...  
End ...  
  
Start ...  
Not allowed  
End ...
```

## Template method pattern

The template method pattern is a design pattern that allows a group of interchangeable, similarly structured, multi-step algorithms to be defined. Each algorithm follows the same series of actions but provides a different implementation of the steps.

This design pattern allows you to change the behavior of a class at run-time. It is almost the same as Strategy design pattern but with a significant difference. While the Strategy design pattern overrides the entire algorithm, Template method allows you to change only some parts of the behavior algorithm using abstract operations (the entire algorithm is separated into several operations).

### Structural code example

The UML diagram below describes an implementation of the template method design pattern. This diagram consists of two parts:

- **AlgorithmBase:** defines abstract primitive operations that concrete subclasses define to implement steps of an algorithm. Implements a template method which defines the skeleton of an algorithm. The template method calls primitive operations as well as operations defined in **AbstractClass** or those of other objects.
- **ConcreteAlgorithm:** implements the primitive operations to carry out subclass-specific steps of the algorithm. When a concrete class is called the template method code will be executed from the base class while for each method used inside the template method will be called the implementation from the derived class.

#### 4.5 Do not use std::string in critical loops

On most platforms, the implementation of the standard string class is poor. This is due to several factors:

- ☐ The internal buffer is aggressively reference counted.
- ☐ The internal buffer is protected by a mutex (sometimes even in a single threaded context).
- ☐ It is sometimes implemented as a wrapper on a lower-level class (Roguewave for instance).

Therefore, using strings should be avoided in critical loops, especially write operations (construction,

assignment, etc... ). However, using only the `c_str()` operator seems to be OK.

**Valgrind:**  
 =====

**Tool = Memcheck**

This tool can detect the following memory related problems :

- Use of uninitialized memory
- Reading/writing memory after it has been freed
- Reading/writing off the end of malloc'd blocks
- Memory leaks
- Mismatched use of malloc/new/new[] vs free/delete/delete[]
- Doubly freed memory

```
valgrind --tool=memcheck --leak-check=full ./val
```

Key checks:

- Invalid read
- Invalid write
- LEAK SUMMARY
- HEAP SUMMARY
- Mismatched free
- Invalid free
- Error
- Uninitialized

<http://easycplusplus.com/cpp/cpptutorial22a.html>

by **John Kopp**

**Support this site at no cost to you**

### Introduction

Welcome to EasyCplusplus.com's free tutorial on C++ programming. This lesson deals with two important keywords, `const` and `mutable`, and their use with class objects. `Const` provides a way to declare that an object is not modifiable. It can also be used with class methods to indicate to they will not modify their objects. The use of "const" can reduce bugs within your code by allowing the compiler to catch unintended modification of objects that should remain constant. The keyword `mutable` provides a way to allow modifications of a particular data members of a constant objects. By the way, I love tabloid style headlines, which is why this lesson is titled "Mutable Members" rather than something dull like "Const and Mutable"

### Const

In an earlier lesson, the keyword `const` was used to declare that an object of built-in type, that is, an ordinary variable, was a constant. Attempts to modify a "const" result in a compilation error.

```
const int limit;  
limit = 25; // Results in compilation error
```

`Assigning` to a `const` variable is not permitted. It must be `initialized` to provide a value.

```
const int limit = 25;
```

This provided a way to have a constant and to be sure that the constant was not modified unintentionally. C++ also allows the declaration of `const` class objects.

```
// Class Definition  
class Employee {  
public:  
    string getName(){return _name;}  
    void setName(string name) {_name = name;}  
    string getId(){return _id;}  
    void setId(string id) {_id = id;}  
private:  
    string _name;  
    string _id;  
};  
  
const Employee john;
```

This declares the object john of class Employee to be constant. But there are problems with this code. First, since the object is const, we need a way to initialize it. Its **members** cannot be assigned either directly or indirectly via **methods**. The compiler's default constructor is insufficient, so we must define constructors that can initialize all the data members. A default constructor that initializes all members is required. Other constructors may be written. Second, C++ allows methods to be declared as const. By declaring a method "const" we are in effect stating that the method cannot change its object. *Only methods declared const can be called on a const object.* This has real benefit. The compiler can check that methods declared const do not modify the object. Attempts to modify an object within a const method will be flagged by the compiler. Since a const object may invoke only const methods, it will not be modified unintentionally. *Objects that are not const can invoke both const and non-const methods.* Which methods should be declared as const? Certainly, any method that is intended to simply return the value of a data member should be. Depending upon their purpose, the const keyword may be appropriate for other methods as well. Let's correct the Employee class to allow its proper use with const Employee objects and see its use in a simple program.

### Operator "<<" overloading - For Debugging purpose

```
#include <iostream>
using namespace std;
```

```
class Test
{
private:
    int i;
    string s;
public:
    Test(int _i, string _s): i(_i), s(_s)
    {}
    friend ostream &operator<<(ostream &out, const Test& t)    //output
    {
        out<<"i: "<<t.i<<"\n";
        out<<"s: "<<t.s<<"\n";
        return out;
    }
};

int main()
{
    Test t1(10,"himanshu");

**Overriding:**

=====

Let me explain this way:

Your dad has a bike and ur his son want to use his bike but it is outdated and u want to modify it the way you want to and ride it...that is, ur dad(class) has a function called Bike and ur using the same Bike(function) but modified/changed and ur using it(overriding). Same bike but now it is changed.... and when we say son it is ur modified bike that shud come into picture ..which has overriden ur dad's old bike

**ObjectCount.cpp**

```
#include <iostream>
using namespace std;
```

```
template <class T>
class ObjectCount
{
    static int count;
protected:
    ObjectCount() {
        count++;
    }
public:
```

```
        void static showCount() {
            cout << count << endl;
        }
};

template <class T>
int ObjectCount<T>::count = 0;

class Employee : public ObjectCount<Employee>
{
    public:
        Employee(){}
        Employee(const Employee & emp) {}
};

class Manager : public ObjectCount<Manager>
{
    public:
        Manager(){}
        Manager(const Manager & man) {}
};

class Director : public ObjectCount<Director>
{
    public:
        Director(){}
        Director(const Director & dir) {}
};

int main()
{
    Employee e[10];
    cout << "Employee's count: ";ObjectCount<Employee>::showCount();
    Manager m[5];
    cout << "Manager's count: ";ObjectCount<Manager>::showCount();
    Director d1;
    cout << "Director's count: ";ObjectCount<Director>::showCount();
}
```

**Output:**

```
Employee's count: 10
Manager's count: 5
Director's count: 1
```
